Class 40, No. 169793SOURCE: Byulleten' izobreteny i tovarnykh znakov, no. 7, 1965, 104TOPIC TAGS: tellurium, tellurium refining, high purity tellurium

ABSTRACT: This Author Certificate introduces a method of refining tellurium up to 99.999% purity. Commercial grade tellurium is purified by distillation, first in hydrogen at 700C and then in a vacuum of 1 mm Hg at a temperature gradually changing from 800C in the still to 500C in the condenser. B

AUTHOR: Zhukov, B. A.; Shadskiy, I. A.; Zhukov, N.

TITLE: Durability of some alloys at high frequencies

SOURCE: Ref. zh. Metallurgiya, Abs. 11559

REF SOURCE: Tr. Kuybyshevsk. aviat. in-t, vyp. 19, 1965, 399-404

TOPIC TAGS: alloy steel, durability, vibration test

ABSTRACT: The authors studied the effect of variable high-frequency loads on the vibration strength of scoop materials (SAP, VT3-1, EI961 and EI617). Fatigue tests were done on an installation of the resonance type with an electromagnetic system for excitation of oscillations from 200 to 2400 cps. Thermal conditions were varied during testing from room temperature to 550°C. It was found that increasing the load frequency increases σ_w for all materials studied. VT3-1 alloy showed the greatest increase in σ_w . V. Ivanova. [Translation of abstract]

AUTHOR: Zhukov, S. A.; Shadskiy, I. A.; Zhukov, N. D.

TITLE: Strength of certain alloys at high frequencies

SOURCE: Ref. zh. Vozdushnyy transport, Abs. 1A72

REF SOURCE: Tr. Kuybyshevsk. aviats. in-t, vyp. 19, 1965, 399-404

TOPIC TAGS: fatigue strength, alloy, fatigue test, METAL ALLOYS, PROPELLER BLADE

ABSTRACT: The study concerned effects of high frequency variable loads on fatigue limit of blade materials (SAP, VT3-1, EI961 and EI617). Fatigue tests employed a resonance setup, using an electromagnetic system to excite oscillations from 200 to 2400 cps. Test temperature varied from room temperature to 550C. It was established that the fatigue limit improves for all tested materials as the loading frequency increases. Best improvement in fatigue limit was noted for alloy VT3-1. Contribution on the Method of Determining Fatigue Strength with High Stress. N. I. Zhukov. (Zavodskaya Laboratoriya, 1949, vol. 15, Aug., pp. 971-978). [In Russian]. Methods are described by which the fatigue strength of normalized or hardened and tempered specimens of several steels were determined using Behnke's fatigue-testing machine. The determination of bending fatigue strength was carried out by finding the energy expended in turning the bent specimen, while the torsional fatigue strength was calculated from the area of the hysteresis loop. The damping capacities of the steels can be calculated from the fatigue values thus obtained.—S. K.

AUTHORS: Zhukov, S. L., Skladnov, I. K., Lapitskiy, Yu. A., Novikov, M. S.

TITLE: Investigating the scale resistance of heat-resistant alloy sheets

SOURCE: Termostoykost' zharoprochnykh splavov, sbornik statey, Ed. by
N. M. Sklyarov Moscow, Oborongiz, 1962, 165 - 169

TEXT: The suitability of sheet materials for the manufacture of combustion chambers was tested on a machine designed by the authors (Author's Certificate no. 89849). The machine makes it possible to check and inspect the sheet material as if under operational conditions. The specimen is heated by passing electric current and cooled by an air jet. The thermal cycles are automatically controlled and their number is registered by a special electric counter. The whole heating-cooling cycle lasts from 30 sec to 2 minutes and more, and depends on the given conditions. One- and two- beveled specimens were tested at temperatures ranging from 200 to 900°C. The specimens were made of alloys X20H80T3 (Kh20N80T3) X20H80T (Kh20N80T) X18H12M2 (Kh18N12M2) X18H11B (Kh18N11B), and chrome steels with 27% Cr and with 5% Ni. The number of thermal cycles until

Card 1/2

Investigating the scale resistance of...

S/853/62/000/000/008/008
A006/A101

the breakdown of specimens was almost twice as low for one-bevel as for two-bevel specimens; it decreased with higher quenching temperatures. At close quenching temperatures, alloy Kh20N80T was found to be more resistant to the effect of thermal cycles than the Kh20N80T3 alloy. The specimens broke down along the grain boundaries without noticeable plastic deformation. Higher quenching temperatures increasing from 1050 to 1,200°C caused the growth of solid solution grains in alloy Kh20N80T and increased ductility at room temperature; ductility was reduced at elevated temperatures. The number of thermal cycles until the appearance of cracks was sharply reduced at higher quenching temperatures. There are 3 tables and 1 figure.

61349 (V sb. "Deformiruyemyye alyumin. splavy". Moscow, Oborongiz,
1961, 150 - 157)

TEXT: Mechanical properties and δ_w of alloys of the Al-Mg-Si system lying on the sections parallel to the sides Al-Mg and Al-Si of concentration triangle were investigated. All alloys had a constant content of 0.35 - 0.4% Mn and 0.17 - 0.2% Cr and were prepared of A00 Al. The ingots, after having been poured into a water-cooled mold, were diffusion-annealed for 24 hours at 470°C and pressed at 470 - 490°C in rods 22 mm in diameter. The heat treatment consisted of 40 min. heating at 520°C in a saltpeter bath, water hardening and artificial ageing at 150°C during 15 hours. It is shown that an increase in percentage of Mg₂Si phase in the solid solution leads to a continuous increase of σ_b and decrease of δ . An excess of Si at a constant Mg and Mg₂Si content increases sharp-

Fatigue strength of aluminum-base alloys

S/137/62/000/006/123/163
A052/A101

ly σ_b and decreases δ . In this case σ_w increases from 8 to 11 kg/mm² only in alloys with 0.8% Mg₂Si. An excess of Mg of up to 0.7% in alloys with 0.8% Mg₂Si contributes to an increase of σ_b and to decrease of δ at a practically constant σ_w . A further increase of Mg content results in a drop of σ_b , σ_w and a rise of δ . In alloys with 1.4 and 1.9% Mg₂Si an increase of Mg to 2% decreases sharply σ_b and increases δ . An increase of Mn content from 0.3 to 0.6% in alloys of 6061 (1.1% Mg + 0.6% Si) and AB (AV) (1.0% Mg + 1.2% Si) types leads to an increase of σ_b and σ_w . The most rational AV alloy composition securing the stability of properties of pressed products is suggested: 0.8 - 1.2% Si, 0.6 - 1.0% Mg, 0.4 - 0.9% Mn. Comparative fatigue strength tests at a cantilever bending of smooth and notched samples carried out on standard AB (AV), АМГ 3 (AMG3), Δ1 (D1), Δ16 (D16), В 95 (V95) and AK 8 (AK8) alloys have shown that AK8, D16 and V95 alloys have maximum σ_w . σ_w of D1, D16 and V95 alloys is in a direct dependence on ageing conditions. In the case of V95 alloy maximum σ_w is reached after 16 hour ageing at 140°C. An addition of Mn or Cr to Al-Mg-Zn or Al-Mg-Zn-Cu alloys contributes to an increase of σ_b , σ_w and to a sharp decrease of δ . However, in alloys with Cr, σ_b and σ_w are lower than in alloys with Mn. A simultaneous presence of 0.35% Mn and 0.16% Cr in V95 alloy makes it possible to ob-

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 11, 1962, 24,
abstract 11A151 (V sb: "Deformiruyemye alyumin. splavy". Moscow,
Oborongiz, 1961, 150 - 157)

TEXT: The effect of structure and of alloying elements (0.3 - 1.1% Si,
0.5 - 2% Mg) on the fatigue strength of Al-alloys of Al-Mg-Si system was studied.
These alloys are applied as a material for longerons of helicopter blades. The
results have shown that an increase of percentage of Mg-phase within its limits
of solubility in the solid solution increases the tensile σ_b and decreases δ .
The maximum fatigue limit have AK 8 (AK8), D16 (D16) and U95 (U95) alloys,
 σ_{-1} depending directly on the conditions of ageing. U 95 (U95) alloy has good
 σ_{-1} characteristics, but at the same time an increased sensitivity to stress con-
centrations which reduces σ_{-1} in ready products.

TITLE: Fatigue resistance of alloys based on Al

SOURCE: Fridlyander, I.N., V.I. Dobatkin, and Ye.D. Zakharov, eds. Deformiruyemye alyuminiyevyye splavy; sbornik statey. Moscow, 1961, 150 - 157

TEXT: A study of the influence of structure and various alloying elements on the fatigue resistance of alloys in the Al-Mg-Si system. The main characteristic which those alloys should possess is a high -fatigue resistance during the action of corrosive media. The specific aim of this work was to establish the influence of Si and Mg on the fatigue limit of the Al-Mg-Si alloys. 10 alloys were investigated 3 corresponding to the quasi-binary section Al-Mg₂Si, 3 with excess Si and 4 with excess Mg with respect to the quasi-binary section. All alloys had a constant content of 0.35 - 0.4 % Mn and 0.17 - 0.20 % Cr. ✓

Card 1/3

Fatigue resistance of alloys based on Al S/680/61/000/000/020/030

A00 (A00) aluminum was used. The ingots were prepared at 700 - 710°C homogenized at 470°C during 24 hours and pressed into 22 mm rods at 470 - 490°C, heated in a saltwater bath for 40 minutes, quenched in water and artificially aged at 150°C during 15 hours. Mechanical testing followed. The increase of Mg₂Si content increases the strength limit and decreases the relative elongation. At constant Mg and Mg₂Si contents, an increase of Si sharply increases the strength limit. Excess of Mg, with respect to the amount in Mg₂Si, increases the strength limit and does not influence the fatigue limits and an increase in the relative elongation. The strength limit of the AP (AV) alloys ranges from 32 to 42 kg/mm². To stabilize the mechanical properties it seems desirable to raise the lower limits of Mg and Si contents and maintain the contents at 0.8 - 1.2 % Si and 0.6 - 1.0 % Mg. The influence of Mn and AV and 6061 type alloys was examined, finding that a Mn increase from 0.3 to 0.6 % increases the strength and fatigue limits. Ti had no effect on the mechanical properties of the alloys and Cu was not needed in the alloy, its absence being compensated by Mn. The alloys AK8, D16 and B95 (V95) have the maximum fatigue limit.

Card 2/3

S/689/61/000/000/020/03
D205/D303

Fatigue resistance of alloys based on Al
gue limits of about 15 kg/mm^2 . It was shown that the fatigue limit is
directly dependent on the ageing regime. For instance, the V95 alloy
has the maximum fatigue limit after ageing at 140°C over 16 hours.
Any change from this regime causes a considerable decrease in the fa-
tigue limit without affecting the strength limit. The influence of
Cu, Mg, Mn and Cr on the fatigue limit of V95 has shown that both Mn
and Cr have a beneficial effect on the mechanical properties. The opti-
mum composition is 2% Cu, 3% Mg, 6% Zn, 0.35% Mn and 0.16% Cr.

TITLE:

Investigation of endurance of titanium-base and other
heat-resistant alloys tested on the ВИУ-1 МАИ-ВИАМ
(VIU-1 MAI-VIAM) machine under high frequency loads

PERIODICAL:

Moscow. Aviatsionnyy institut. Trudy, No.129, 1960.
Issledovaniye fizikomekhanicheskikh i ekspluatatsionnykh
svyazей detaley posle obrabotki, pp. 92-111

TEXT:

The object of the investigation described in the present paper was to determine the endurance limit of a titanium alloy BT3-1 (VT3-1) and two nickel-base alloys of the 9Н617 (EI617) and 9К6К (ZhS6K) type, and to study the effect of the frequency of alternating loads on this property. The main shortcoming of the conventional fatigue testing methods is that the test conditions bear little relation to the conditions obtaining in service; in addition, they are time-consuming, 4-5 months of continuous work being required to construct on fatigue curve. It was for these reasons that a high frequency testing machine (VIU-1 MAI-VIAM) was

Card 1/9

Investigation of endurance of ...

X

used in the present investigation. The machine (whose detailed description is given) is of the resonance type and was designed for single-plane bending fatigue tests which can be carried out under the conditions of both imposed and resonance vibrations. The vibrations, generated by a powerful electromagnetic system consisting of an amplifier and a transformer, are transmitted to the test piece through a heavy beam, capable of producing alternating loads which are sufficiently high to break standard test pieces or even actual components, such as turbine blades. The auxiliary equipment consists of a microscope used for setting the test piece and for measuring the vibration amplitude which at high temperatures is measured with the aid of a cathetometer, and an electrical resistance furnace for high temperature work. Before testing, the test pieces were heat treated according to schedules given in Table 2. The tests were carried out on cylindrical test pieces of the cantilever type. The gauge length ℓ of the test pieces varied depending on the load frequency and test temperature, and was calculated from the formula

Card 2/9

$$\ell = \sqrt{\frac{(1.8751)^2}{2\pi f}} \sqrt{\frac{EJ}{m}}$$

Investigation of endurance of ...

where f is the vibration frequency per sec, E the modulus of elasticity (kg/mm^2), J the moment of inertia (mm^4), and m mass per unit length ($\text{kg.sec}^2/\text{mm}^2$). The tests were conducted on a base $N = 10^8$ cycles in the case of the EI617 and ZhS6K alloys, and 10^7 cycles in the case of the VT3-1 alloy. Each fatigue curve was constructed from data obtained on eight test pieces. In the first test of each series a stress equal approximately to $0.5 \sigma_b$ was used, where σ_b is the U.T.S. of the alloy tested; in each subsequent test the applied stress was lowered by 2 kg/mm^2 . The vibration amplitude, A (mm), of the free end of the test piece, required to produce a given stress, was calculated from the formula

$$A = 0.5682 \frac{\ell^2}{Ed} \sigma,$$

where ℓ and d are the length and diameter of the specimen, respectively, E the modulus of elasticity (kg/mm^2), and σ , the applied stress (kg/mm^2). The results are reproduced in Figs.10-13, where the stress σ_{-1} (kg/mm^2) is plotted against the number of cycles to fracture. The fatigue curves in Fig.10 relate to alloy EI617, tested at 20°C under the following conditions: (1) testing

Card 3/9

S/535/60/000/129/005/006

E193/E580

machine of the ГЗИП (GZIP) type (bending of the revolving specimen), load frequency $f = 50$ cycles/sec; (2) testing machine of the П-391 (P-391) type (bending of a revolving specimen), $f = 200$ cycles/sec, (3) testing machine VIU-1 MAI-VIAM (single plane bending), $f = 1000$ cycles/sec. The fatigue curves in Fig.11 relate to alloy ZhS6K tested at 20°C , the testing conditions for curves 1-3 being the same as in Fig.10. The results, reproduced in Fig.12 relate to alloy VT3-1 tested under the following conditions: curve 1 - testing machine VIU-1 MAI-VIAM, $f = 1100$ cycles/sec, $t = 20^\circ\text{C}$; curve 2 - same as for curve 1, except $f = 420$ cycles/sec; curve 3 - testing machine GZIP, $f = 50$ cycles/sec, $t = 20^\circ\text{C}$; curve 4 - testing machine VIU-1 MAI-VIAM, $f = 420$ cycles/sec, $t = 400^\circ\text{C}$. Fig.13 shows the fatigue curves of the VT3-1 alloy, tested at 20°C on the VIU-1 MAI-VIAM machine, curves 1-3 relating to tests carried out at $f = 450$, 1100 and 1650 cycles/sec, respectively; these are the most significant results of the present investigation, showing that the endurance limit of the alloys studied increased with increasing load frequency. Metallographic examination of the fatigue test pieces in the region of fracture revealed no changes in the microstructure

Card 4/9

E193/E580

due to increased loading frequency. The fatigue cracks were trans-crystalline, and only in the zone of final fracture were intergranular cracking and some degree of plastic deformation of the grains observed. It was concluded that both the equipment used and the method employed by the present authors are suitable for fatigue testing under high frequency loading and give reliable results which can be used as design data in the production of turbine and compressor blades, operating under high frequency loads. Abstract: A large number of varieties are cultivated under the variegated soil and climatic conditions of the country. Officially, the classification by regions has not yet been completed; however, 177 of the best varieties have been separated. Flint wheat is produced on 80% of the entire sowing area. Chiefly the dent varieties are grown in the northern regions.
